

Koszul Almost Complete Intersections

Matthew Mastroeni

Abstract

Let $R = S/I$ be a quotient of a standard graded polynomial ring S by an ideal I generated by quadrics. If R is Koszul, a question of Avramov, Conca, and Iyengar asks whether the Betti numbers of R over S can be bounded above by binomial coefficients on the minimal number of generators of I . Motivated by previous results for Koszul algebras defined by three quadrics, we give a complete classification of the structure of Koszul almost complete intersections and, in the process, give an affirmative answer to the above question for all such rings.

1 Introduction

Let k be a field, S be a standard graded polynomial ring over k , $I \subseteq S$ be a graded ideal, and $R = S/I$. We say that R is a *Koszul algebra* if $k \cong R/R_+$ has a linear free resolution over R . Many rings arising from algebraic geometry are Koszul, including the coordinate rings of Grassmannians [Kem90], sets of $r \leq 2n$ points in general position in \mathbb{P}^n [Kem92], and canonical embeddings of smooth curves under mild restrictions [Pol95], as well as all suitably high Veronese subrings of any standard graded algebra [Bac86]. However, the simplest examples of Koszul algebras, due to Fröberg [Fro75], are quotients by quadratic monomial ideals, and a guiding heuristic in the study of Koszul algebras has been that any reasonable property of algebras defined by quadratic monomial ideals should also hold for Koszul algebras; for example, see [ACI10], [Con14], [ACI15]. Among such properties, considering the Taylor resolution for an algebra defined by a quadratic monomial ideal leads to the following question about the Betti numbers of a Koszul algebra.

Question 1.1 ([ACI10, 6.5]). If R is Koszul and I is minimally generated by g elements, does the following inequality hold for all i ?

$$\beta_i^S(R) \leq \binom{g}{i}$$

In particular, is $\mathrm{pd}_S R \leq g$?

The above questions are known to have affirmative answers when R is LG-quadratic (see next section) and for arbitrary Koszul algebras when $g \leq 3$ by [BHI16, 4.5]. Recall that R or I is called an *almost complete intersection* if I is minimally generated by $\mathrm{ht} I + 1$ elements.

The motivation for studying Koszul almost complete intersections comes from the fact that the above question holds trivially when I is a complete intersection or has height one so that the interesting case for Koszul algebras defined by three quadrics is precisely when I is an almost complete intersection. Our main results (3.1, 3.3, 3.4, 4.3) show that Question 1.1 has an affirmative answer for Koszul almost complete intersections generated by any number of quadrics; they are summarized in the theorem below.

Main Theorem. *Let $R = S/I$ be a Koszul almost complete intersection with I minimally generated by $g + 1$ quadrics for some $g \geq 1$. Then $\beta_{2,3}^S(R) \leq 2$, and:*

- (a) *If $\beta_{2,3}^S(R) = 1$, there are linear forms x, z , and w such that $I = (xz, zw, q_3, \dots, q_{g+1})$ for some regular sequence of quadrics q_3, \dots, q_{g+1} on $S/(xz, zw)$.*
- (b) *If $\beta_{2,3}^S(R) = 2$, there is a 3×2 matrix of linear forms M with $\text{ht } I_2(M) = 2$ such that $I = I_2(M) + (q_4, \dots, q_{g+1})$ for some regular sequence of quadrics q_4, \dots, q_{g+1} on $S/I_2(M)$.*

Furthermore, R is LG-quadratic and, therefore, satisfies $\beta_i^S(R) \leq \binom{g+1}{i}$ for all i .

The division of the rest of the paper is as follows. We recount various properties and examples of Koszul algebras and their Betti tables in §2 which will be important in the sequel. In §3, we determine the structure of Koszul almost complete intersections with either one or two linear second syzygies. We then complete the classification of Koszul almost complete intersections in §4 by showing that every quadratic almost complete intersection has at most two linear second syzygies.

Notation. Throughout the remainder of the paper, the following notation will be in force unless specifically stated otherwise. Let k be a fixed ground field of arbitrary characteristic, S be a standard graded polynomial ring over k , $I \subseteq S$ be a proper graded ideal, and $R = S/I$. Recall that the ideal I is called *nondegenerate* if it does not contain any linear forms. We can always reduce to a presentation for R with I nondegenerate by killing a basis for the linear forms contained in I , and we will assume that this is the case throughout. We denote the irrelevant ideal of R by $R_+ = \bigoplus_{n \geq 1} R_n$.

2 Koszul Algebras and Their Betti Tables

If R is a Koszul algebra, it is well-known that its defining ideal I must be generated by quadrics, but not every ideal generated by quadrics defines a Koszul algebra. We have already noted in the introduction that every quadratic monomial ideal defines a Koszul algebra. More generally, we say that R or I is *G-quadratic* if, after a suitable linear change of coordinates $\varphi : S \rightarrow S$, the ideal $\varphi(I)$ has a Gröbner basis consisting of quadrics. We also say that R or I is *LG-quadratic* if R is a quotient of a G-quadratic algebra A by an A -sequence of linear forms. Every G-quadratic algebra is Koszul by upper semicontinuity of

the Betti numbers; see [BC03, 3.13]. It then follows from Proposition 2.4 below that every LG-quadratic algebra is also Koszul. In particular, every complete intersection generated by quadrics is LG-quadratic by an argument due to Caviglia. Indeed, if $R = S/(q_1, \dots, q_g)$ where q_1, \dots, q_g is a regular sequence of quadrics, we can take $A = S[y_1, \dots, y_g]/(y_1^2 + q_1, \dots, y_g^2 + q_g)$ so that $A/(y_1, \dots, y_g) \cong R$. By choosing a monomial order in which the y_i are greater than every monomial in the variables of S , it follows from [Eis95, 15.15] that A is G-quadratic and that the $y_i^2 + q_i$ form a regular sequence so that $\text{ht}_A(y_1, \dots, y_g) = \dim A - \dim R = \dim S - \dim R = g$ and y_1, \dots, y_g is an A -sequence. In summary, we have the following implications.

$$\begin{array}{c} \text{G-quadratic} \implies \text{LG-quadratic} \implies \text{Koszul} \\ \uparrow \\ \text{Quadratic CI's} \end{array}$$

Each of the above implications is strict. Clearly, any quadratic monomial ideal which is not a complete intersection, such as $(xy, xz, xw) \subseteq k[x, y, z, w]$, is LG-quadratic. In [Con14, 1.14], it is observed that $(x^2 + yz, y^2 + xz, z^2 + xy) \subseteq \mathbb{Q}[x, y, z]$ is an Artinian quadratic complete intersection which cannot be G-quadratic since it does not contain the square of a linear form. We will see an example of a Koszul algebra which is not LG-quadratic below.

Remark 2.1. If $R = S/I$ is G-quadratic and J is a quadratic initial ideal of I , then $\beta_1^S(R) = \beta_1^S(S/J)$ since I is generated by quadrics and R and S/J have the same Hilbert function. Consequently, $\beta_i(R) \leq \beta_i(S/J) \leq \binom{g}{i}$ for all i by upper semicontinuity of the Betti numbers and the Taylor resolution for S/J . Since killing a regular sequence of linear forms does not affect the Betti numbers of R , it follows that Question 1.1 holds for every LG-quadratic algebra.

We will be specifically interested in the *graded Betti numbers* of a Koszul algebra R , which are defined by $\beta_{i,j}^S(R) = \dim_k \text{Tor}_i^S(k, R)_j$ and related to the usual Betti numbers by $\beta_i^S(R) = \sum_j \beta_{i,j}^S(R)$. This information is usually organized into a table, called the Betti table of R ; see below for an example. As we have already pointed out in the introduction, quadratic monomial ideals serve as a useful benchmark in the study of Koszul algebras. In particular, we note that the square-free quadratic monomial ideals are precisely edge ideals. Recall that, if G is a graph with vertex set $[n] = \{1, \dots, n\}$, the *edge ideal* of G is the ideal of the polynomial ring $S = k[x_1, \dots, x_n]$ defined by $I_G = (x_i x_j \mid ij \in E(G))$. We note that every quadratic monomial ideal can be obtained as the image of an edge ideal modulo a regular sequence of linear forms via polarization [BH93, 4.2.16], and hence, studying the Betti tables of all quadratic monomial ideals with g generators is equivalent to studying the Betti tables of edge ideals of graphs with g edges, which are reasonably simple to enumerate in practice for small values of g .

In fact, a byproduct of the proof in [BHI16] that every Koszul algebra defined by $g \leq 3$ quadrics satisfies Question 1.1 is that every such algebra has the Betti table of some edge

ideal. This suggests taking the Betti tables of edge ideals as our guide for exploring possible patterns in Betti tables of Koszul algebras with more generators. One can then easily compute that, for various values of g , there are only two possible Betti tables for almost complete intersection edge ideals with g generators, one with a single linear syzygy and another with two. The purpose of this paper is to show that this pattern holds more generally for all Koszul almost complete intersections. However, the following example shows that the mantra that Koszul algebras are similar to quotients by quadratic monomial ideals must be taken with a grain of salt.

Example 2.2 ([Con14, 3.8]). The ring $R = k[x, y, z, w]/(xy, xw, (x - y)z, z^2, x^2 + zw)$ is Koszul by a filtration argument. The minimal free resolution of R over $S = k[x, y, z, w]$ can be computed via iterated mapping cones using the fact that $((xy, xw, z^2) : (x - y)z) = (xy, xw, z)$ and $((xy, xw, z^2, (x - y)z) : x^2 + zw) = (xw, y, z)$. This yields the following Betti table for R , where the entry in column i and row j is $\beta_{i,i+j}^S(R)$ and zero entries are represented by “–” for readability.

	0	1	2	3	4
0	1	–	–	–	–
1	–	5	4	–	–
2	–	–	4	6	2

From the above Betti table, we see that the Hilbert series of R is

$$H_R(t) = \frac{1 + 2t - 2t^2 - 2t^3 + 2t^4}{(1 - t)^2}$$

If R were LG-quadratic, then the numerator of the Hilbert series must be the h -polynomial of a 5-generated edge ideal, since killing a regular sequence of linear forms and passing to a quadratic initial ideal do not change either the h -polynomial or the minimal number of generators of the defining ideal. As noted above, we can easily compute that the h -polynomial of R does not belong to any 5-generated edge ideal. Hence, R is not LG-quadratic, and in particular, the Betti table of R is not the Betti table of any edge ideal. This points to unexpected complications in trying to answer Question 1.1 for Koszul algebras defined by $g \geq 5$ quadrics.

Remark 2.3. We can compute the Betti tables of 5-generated edge ideals in the above example over a field of any characteristic by a result of Katzman, [Kat06, 4.1]. However, Katzman also shows that the Betti tables of edge ideals do depend on the characteristic of the ground field in general.

In the remainder of this section, we collect a few results about Koszul algebras that will be useful in the sequel. The first of these results states how the Koszul property can be passed to and from quotient rings.

Proposition 2.4 ([CDR13, §3.1, 2]). *Let S be a standard graded k -algebra and R be a quotient ring of S .*

- (a) *If S is Koszul and $\operatorname{reg}_S(R) \leq 1$, then R is Koszul.*
- (b) *If R is Koszul and $\operatorname{reg}_S(R)$ is finite, then S is Koszul.*

Compared with general quadratic algebras, the Betti tables of Koszul algebras are much more restricted. The following result, discovered in [Bac88] and [Kem90, 4], says that the Betti tables of Koszul algebras have nonzero entries only on or above the diagonal; see [Con14, 2.10] for an easier argument using regularity.

Lemma 2.5. *If $R = S/I$ is a Koszul algebra, then $\beta_{i,j}^S(R) = 0$ for all i and $j > 2i$.*

In addition, the extremal portions of the Betti table of a Koszul algebra R , namely the diagonal entries and the linear strand of I , satisfy bounds similar to those in Question 1.1.

Proposition 2.6 ([BHI16, 3.4, 4.2]). *Suppose that $R = S/I$ is Koszul and that I is minimally generated by g elements. Then:*

- (a) *$\beta_{i,i+1}^S(R) \leq \binom{g}{i}$ for $2 \leq i \leq g$, and if equality holds for $i = 2$, then I has height one and a linear resolution of length g .*
- (b) *$\beta_{i,2i}^S(R) \leq \binom{g}{i}$ for $2 \leq i \leq g$, and if equality holds for some i , then I is a complete intersection.*

Corollary 2.7. *If $R = S/I$ is a Koszul algebra which is not a complete intersection, then I has a linear syzygy.*

Proof. Suppose that I is minimally generated by q_1, \dots, q_g . If the Koszul syzygies on the q_i are all minimal generators of $\operatorname{Syz}_1^S(I)$, then $\beta_{2,4}^S(R) \geq \binom{g}{2}$ contradicting the preceding proposition. Hence, some k -linear combination of the Koszul syzygies is not minimal, and therefore, it is an S -linear combination of linear syzygies. \square

Lastly, we will need a fact about the syzygies of a Koszul algebra which will be clear to experts, but for completeness, we give a quick proof. The proof relies on the product structure on $\operatorname{Tor}_*^S(R, k)$. We briefly recall how this product is defined and refer the reader to [Avr98] for further details. To simplify notation, all tensor products below are over S .

If F_\bullet denotes the minimal free resolution of R over S , we have the Künneth map

$$\operatorname{Tor}_i^S(R, k) \otimes \operatorname{Tor}_j^S(R, k) = H_i(F_\bullet \otimes k) \otimes H_j(F_\bullet \otimes k) \xrightarrow{\kappa} H_{i+j}((F_\bullet \otimes k) \otimes (F_\bullet \otimes k))$$

sending $\operatorname{cls}(v) \otimes \operatorname{cls}(w) \mapsto \operatorname{cls}(v \otimes w)$. Denoting by $\mu^k : k \otimes k \rightarrow k$ and $\mu^R : R \otimes R \rightarrow R$ the respective product maps, we have a chain map $\mu^F : F_\bullet \otimes F_\bullet \rightarrow F_\bullet$ lifting μ^R . The product structure on $\operatorname{Tor}_*^S(R, k)$ is the composition of the Künneth map with the map induced on homology by the chain map

$$F_\bullet \otimes k \otimes F_\bullet \otimes k \cong F_\bullet \otimes F_\bullet \otimes k \otimes k \xrightarrow{\mu^F \otimes \mu^k} F_\bullet \otimes k$$

Proposition 2.8. *If $R = S/I$ is a Koszul algebra, then $\text{Syz}_1^S(I)$ is minimally generated by linear syzygies and Koszul syzygies.*

Proof. By Lemma 2.5, we know that $\text{Syz}_1^S(I)$ is minimally generated by linear and quadratic syzygies. We may assume that $\beta_{2,4}^S(R) \neq 0$ or else the conclusion holds trivially. In that case, it follows from [ACI10, 3.1] that $\text{Tor}_2^S(R, k)_4 = (\text{Tor}_1^S(R, k)_2)^2$, so it suffices to note that the products of the generators of $\text{Tor}_1^S(R, k)_2$ correspond to the Koszul syzygies on a minimal set of generators q_1, \dots, q_g for I . If e_1, \dots, e_g denotes the standard basis of $S(-2)^g = F_1$ such that $\partial(e_i) = q_i$ for each i , we can choose μ^F so that $\mu^F(e_i \otimes 1) = \mu^F(1 \otimes e_i) = e_i$ for all i . Since the $e_i \otimes 1$ span $\text{Tor}_1^S(R, k)_2$, it follows that the $\mu^F(e_i \otimes e_j) \otimes 1$ span $\text{Tor}_2^S(R, k)_4$. As μ^F is a chain map, we see that

$$\partial(\mu^F(e_i \otimes e_j)) = \mu^F(\partial(e_i \otimes e_j)) = \mu^F(q_i \otimes e_j - e_i \otimes q_j) = q_i e_j - q_j e_i$$

so that $\mu^F(e_i \otimes e_j)$ corresponds to a Koszul syzygy in $\text{Syz}_1^S(I)$ as wanted. Hence, the Koszul syzygies together with multiples of the linear syzygies must span $\text{Syz}_1^S(I)_4$, and the proposition easily follows. \square

3 Koszul Almost Complete Intersections

Recall that a standard graded k -algebra $R = S/I$ with $\text{ht } I = g$ is called an *almost complete intersection* (or ACI for short) if I is minimally generated by $g + 1$ elements.

Theorem 3.1. *Let $R = S/I$ be a Koszul algebra with $\beta_{2,3}^S(R) = 1$. Then there are independent linear forms x and w and a linear form z such that $I = (xz, zw, q_3, \dots, q_{g+1})$ for some regular sequence of quadrics q_3, \dots, q_{g+1} on $S/(xz, zw)$, and conversely, every ideal of this form defines a Koszul algebra with $\beta_{2,3}^S(R) = 1$. Hence, R is an almost complete intersection with $e(R) = 2^{g-1}$ and Betti table*

	0	1	2	3	\dots	$g-1$	g	$g+1$
0	1	—	—	—		—	—	—
1	—	$g+1$	1	—		—	—	—
2	—	—	$\frac{g+2}{2} \binom{g-1}{1}$	$\binom{g-1}{1}$		—	—	—
\vdots				\ddots	\ddots			
$g-1$	—	—	—			$\frac{2g-1}{g-1} \binom{g-1}{g-2}$	$\binom{g-1}{g-2}$	—
g	—	—	—			—	2	1

Specifically, we have $\beta_{i,2i}^S(R) = \frac{g+i}{i} \binom{g-1}{i-1}$ and $\beta_{i,2i-1}^S(R) = \binom{g-1}{i-2}$ for $i \geq 2$ so that $\beta_i^S(R) = \binom{g+1}{i}$ for all i .

Proof. Since I has a linear syzygy, it is not a complete intersection. In particular, we can write $I = (q_1, \dots, q_{g+1})$ for some linear independent quadrics q_i with $g \geq 1$. Let $U = \text{Syz}_1^S(I)$,

$W \subseteq U_4$ denote the k -span of the Koszul syzygies on the q_i , and $\ell \in U$ denote the unique linear syzygy up to scalar multiple. If $W \cap S_+U = 0$, then $\beta_{2,4}^S(R) \geq \binom{g+1}{2}$ so that Proposition 2.6 implies I is a complete intersection, which is a contradiction. Hence, there is a linear form z such that $z\ell \in W$ is nonzero. Write $z\ell = \sum_{1 \leq i < j \leq g+1} a_{i,j}(q_j e_i - q_i e_j)$ for some $a_{i,j} \in k$, where e_1, \dots, e_{g+1} denotes the standard basis of $S(-2)^{g+1}$. After suitably relabeling the q_i and rescaling the equality, we may assume that $a_{1,2} = 1$. Reading off the first two coordinates of the preceding equality then gives $z\ell_1 = q_2 + \sum_{j=3}^{g+1} a_{1,j}q_j$ and $z\ell_2 = -q_1 + \sum_{j=3}^{g+1} a_{2,j}q_j$. Using these equalities, we can replace q_1 and q_2 with $z\ell_2$ and $z\ell_1$ as generators of I and assume that $q_1 = xz$ and $q_2 = zw$ for some linear forms x, z , and w . Note that x and w must be independent since the q_i are.

After making this change, we have $\ell = (w, -x, 0, \dots, 0)$ is the unique linear syzygy on the q_i , and $(q_2, -q_1, 0, \dots, 0) = z\ell$. Let $W' \subseteq U_4$ denote the k -span of the Koszul syzygies other than $(q_2, -q_1, 0, \dots, 0)$. If $W' \cap S_+U \neq 0$, then there is a linear form v such that $v\ell \in W'$ is nonzero. Write

$$v\ell = \sum_{\substack{1 \leq i < j \leq g+1 \\ j \geq 3}} b_{i,j}(q_j e_i - q_i e_j)$$

for some $b_{i,j} \in k$. Since $b_{i,j} \neq 0$ for some $j \geq 3$, reading off the j -th coordinate of the above equality yields a linear dependence relation on the q_i , which is a contradiction. Hence, we must have $W' \cap S_+U = 0$ so that all of the Koszul syzygies except $(q_2, -q_1, 0, \dots, 0)$ are part of a minimal set of generators for U . Because $\beta_{2,4}^S(R) \leq \binom{g+1}{2} - 1$ and $\beta_{2,j}^R(S) = 0$ for $j > 4$ by Lemma 2.5, it follows that $U = \text{Syz}_1^S(I)$ is minimally generated by all the Koszul syzygies on the q_i , except $(q_2, -q_1, 0, \dots, 0)$, together with the linear syzygy ℓ .

If $f_{g+1} \in ((xz, zw, q_3, \dots, q_g) : q_{g+1})$, then we can write $f_{g+1}q_{g+1} = -\sum_{i=1}^g f_i q_i$ for some $f_i \in S$ so that $(f_1, \dots, f_{g+1}) \in U$. It follows from the preceding paragraph that $f_{g+1} \in (xz, zw, q_3, \dots, q_g)$ so that q_{g+1} is regular on $R' = S/(xz, zw, q_3, \dots, q_g)$. As $\text{reg}_{R'} R = 1$, it follows from Corollary 2.4 that R' is also Koszul. Moreover, because we can obtain the resolution of R over S by taking the mapping cone of multiplication by q_{g+1} on the resolution of R' over S , it follows that $\beta_{2,3}^S(R') = 1$ and that $(w, -x, 0, \dots, 0)$ is the unique linear syzygy on xz, zw, q_3, \dots, q_g . Hence, induction on g implies that q_3, \dots, q_{g+1} is a regular sequence on $S/(xz, zw)$. Conversely, if $I = (xz, zw, q_3, \dots, q_{g+1})$ for some regular sequence of quadrics q_3, \dots, q_{g+1} on $S/(xz, zw)$, it also follows from Corollary 2.4 that $R = S/I$ is Koszul since $S/(xz, zw)$ is Koszul.

From the preceding paragraph, we see that $\text{ht } I = \text{ht}(xz, zw) + g - 1 = g$ so that I is an almost complete intersection. If F_\bullet denotes the minimal free resolution of $S/(xz, zw)$ over S , we obtain the minimal resolution of R by repeatedly taking the mapping cone of multiplication by q_{i+1} on the resolution of $S/(xz, zw, q_3, \dots, q_i)$. Since taking the mapping cone of multiplication by q_{i+1} is the same as tensoring with the Koszul complex on q_{i+1} , we see that $F_\bullet \otimes_S K_\bullet(q_3, \dots, q_{g+1})$ is the minimal free resolution of R over S , from which the

Betti table is easily deduced. In particular, we have

$$\beta_i^S(R) = \frac{g+i}{i} \binom{g-1}{i-1} + \binom{g-1}{i-2} = \binom{g}{i} + \binom{g}{i-1} = \binom{g+1}{i}$$

Similarly, we note that the multiplicity of $S/(xz, zw, q_3, \dots, q_{i+1})$ is twice the multiplicity of $S/(xz, zw, q_3, \dots, q_i)$, and so, since $e(S/(xz, zw)) = 1$, we see that $e(R) = 2^{g-1}$. \square

Remark 3.2. In the statement of the above theorem, we can choose x and w so that zw, q_3, \dots, q_{g+1} is a maximal S -regular sequence contained in I . Indeed, since q_3, \dots, q_{g+1} is a regular sequence on $S/(xz, zw)$, we know that q_3, \dots, q_{g+1} is a regular sequence on S by Auslander's Zerodivisor Theorem, which is a consequence of the Peskine-Szpiro Intersection Theorem for arbitrary Noetherian local rings and follows from results of Serre in the regular case; see [PS73, II.0]. Each associated prime of (q_3, \dots, q_{g+1}) cannot contain both xz and zw , otherwise we would have $\text{ht } I \leq g-1$ since the former ideal is unmixed. If either of xz or zw is not contained in every associated prime of (q_3, \dots, q_{g+1}) , we are done after possibly switching the roles of x and w . Otherwise, if xz and zw are both contained in different associated primes of (q_3, \dots, q_{g+1}) , then we can replace w with $w + x$.

Theorem 3.3. *Let $R = S/I$ be a Koszul almost complete intersection with $\beta_{2,3}^S(R) = 2$. Then there is a 3×2 matrix of linear forms M with $\text{ht } I_2(M) = 2$ such that $I = I_2(M) + (q_4, \dots, q_{g+1})$ for some regular sequence of quadrics q_4, \dots, q_{g+1} on $S/I_2(M)$, and conversely, every ideal of this form defines a Koszul almost complete intersection with $\beta_{2,3}^S(R) = 2$. Hence, R has multiplicity $e(R) = 3 \cdot 2^{g-2}$ and Betti table*

	0	1	2	3	\dots	$g-2$	$g-1$	g
0	1	—	—	—		—	—	—
1	—	$g+1$	2	—		—	—	—
2	—	—	$3\binom{g-2}{1} + \binom{g-2}{2}$	$2\binom{g-2}{1}$		—	—	—
\vdots				\ddots	\ddots			
$g-2$	—	—	—			$3\binom{g-2}{g-3} + 1$	$2\binom{g-2}{g-3}$	—
$g-1$	—	—	—			—	3	2

Specifically, we have $\beta_{i,2i}^S(R) = 3\binom{g-2}{i-1} + \binom{g-2}{i}$ and $\beta_{i,2i-1}^S(R) = 2\binom{g-2}{i-2}$ for $i \geq 2$ so that $\beta_i^S(R) \leq \binom{g+1}{i}$ for all i .

Proof. Since I has a linear syzygy, it is not a complete intersection. In particular, we can write $I = (q_1, \dots, q_{g+1})$ for some linear independent quadrics q_i with $g \geq 1$. In fact, we must have $g \geq 2$ since it is easily seen that a 2-generated graded ideal cannot have two independent linear syzygies. Let $U = \text{Syz}_1^S(I)$, $W \subseteq U_4$ denote the k -span of the Koszul syzygies on the q_i , and $\ell, h \in U$ denote independent linear syzygies. Arguing as in the proof of the previous theorem, we see there are linear forms z and v such that $z\ell + vh \in W$ is nonzero. Write $z\ell + vh = \sum_{1 \leq i < j \leq g+1} a_{i,j}(q_j e_i - q_i e_j)$ for some $a_{i,j} \in k$, where e_1, \dots, e_{g+1}

denotes the standard basis of $S(-2)^{g+1}$. After suitably relabeling the q_i and rescaling the equality, we may assume that $a_{1,2} = 1$. Reading off the coordinates of the preceding equality then gives

$$\begin{aligned}\tilde{q}_2 &= z\ell_1 + vh_1 = q_2 + \sum_{j=3}^{g+1} a_{1,j}q_j \\ -\tilde{q}_1 &= z\ell_2 + vh_2 = -q_1 + \sum_{j=3}^{g+1} a_{2,j}q_j \\ z\ell_p + vh_p &= -\sum_{i<p} a_{i,p}q_i + \sum_{i>p} a_{p,i}q_i \quad (p \geq 3)\end{aligned}$$

Using the above equalities, we can replace q_1 and q_2 with \tilde{q}_1 and \tilde{q}_2 as generators for I . As a result, we must also replace ℓ with $\tilde{\ell} = (\ell_1, \ell_2, \ell_3 - a_{1,3}\ell_2 + a_{2,3}\ell_1, \dots, \ell_{g+1} - a_{1,g+1}\ell_2 + a_{2,g+1}\ell_1)$ since

$$0 = \sum_{j=1}^{g+1} \ell_j q_j = \ell_1 \tilde{q}_1 + \ell_2 \tilde{q}_2 + \sum_{j=3}^{g+1} (\ell_j - a_{1,j}\ell_2 + a_{2,j}\ell_1) q_j$$

Similarly, h must be replaced with the linear syzygy \tilde{h} defined as above. It is easily seen that $\tilde{\ell}$ and \tilde{h} must also be independent linear syzygies. Finally, setting $b_{i,j} = a_{i,j} + a_{1,j}a_{2,i} - a_{1,i}a_{2,j}$ for $3 \leq i < j \leq g+1$, we claim that

$$z\tilde{\ell} + v\tilde{h} = (\tilde{q}_2, -\tilde{q}_1, 0, \dots, 0) + \sum_{3 \leq i < j \leq g+1} b_{i,j}(q_j e_i - q_i e_j)$$

By definition of \tilde{q}_1 and \tilde{q}_2 , it suffices to check equality in the p -th coordinate for $p \geq 3$. Using the above equalities, we see that

$$\begin{aligned}z\tilde{\ell}_p + v\tilde{h}_p &= z\ell_p + vh_p + a_{1,p}\tilde{q}_1 + a_{2,p}\tilde{q}_2 \\ &= -\sum_{3 \leq i < p} a_{i,p}q_i + \sum_{i>p} a_{p,i}q_i - \sum_{i=3}^{g+1} a_{1,p}a_{2,i}q_i + \sum_{i=3}^{g+1} a_{2,p}a_{1,i}q_i \\ &= -\sum_{3 \leq i < p} (a_{i,p} + a_{1,p}a_{2,i} - a_{2,p}a_{1,i})q_i + \sum_{i>p} (a_{p,i} - a_{1,p}a_{2,i} + a_{2,p}a_{1,i})q_i \\ &= -\sum_{3 \leq i < p} b_{i,p}q_i + \sum_{i>p} b_{p,i}q_i\end{aligned}$$

as required. Hence, after replacing q_1 and q_2 as above, we may assume that $q_1 = -(z\ell_2 + vh_2)$, $q_2 = z\ell_1 + vh_1$, and $a_{1,j} = a_{2,j} = 0$ for all $j \geq 3$.

If $a_{i,j} \neq 0$ for some $3 \leq i < j \leq g+1$, then after relabeling the q_i we may assume that $a_{3,4} \neq 0$. Since $a_{1,j} = a_{2,j} = 0$ for all $j \geq 3$, arguing as in the preceding paragraph shows that we can replace q_3 and q_4 with $-(z\ell_4 + vh_4)$ and $z\ell_3 + vh_3$ respectively so that $I \subseteq (z, v, q_5, \dots, q_{g+1})$ has height at most $g-1$ by Krull's Height Theorem, contradicting

that I is an almost complete intersection. Therefore, $a_{i,j} = 0$ for $3 \leq i < j \leq g+1$, and we see that $(q_2, -q_1, 0, \dots, 0) = z\ell + vh$ for some linear forms z and v .

Suppose first that z and v are independent linear forms. Then $z\ell_i + vh_i = 0$ for $i > 2$ implies that $(\ell_i, h_i) = a_i(v, -z)$ for some $a_i \in k$ so that $\ell = (\ell_1, \ell_2, a_3v, \dots, a_{g+1}v)$ and $h = (h_1, h_2, -a_3z, \dots, -a_{g+1}z)$. If $a_i = 0$ for all i , then we would have two independent linear syzygies on q_1 and q_2 , which we have already noted is impossible above. Hence, after relabeling, we may assume that $a_3 \neq 0$. Replacing q_3 with $a_3q_3 + \dots + a_{g+1}q_{g+1}$, we may assume that $\ell = (\ell_1, \ell_2, v, 0, \dots, 0)$ and $h = (h_1, h_2, -z, 0, \dots, 0)$. Therefore, we have $q_1 = -(z\ell_2 + vh_2)$ and $q_2 = z\ell_1 + vh_1$, and furthermore, $zq_3 = h_1q_1 + h_2q_2 = z(\ell_1h_2 - \ell_2h_1)$ implies $q_3 = \ell_1h_2 - \ell_2h_1$ so that $I = I_2(M) + (q_4, \dots, q_{g+1})$ where M is the matrix

$$M = \begin{pmatrix} \ell_1 & h_1 \\ \ell_2 & h_2 \\ v & -z \end{pmatrix} \quad (3.1)$$

Suppose now that $v = cz$ for some $c \in k$. Then after replacing ℓ with $\ell + ch$, we may assume that $(q_2, -q_1, 0, \dots, 0) = z\ell$ so that $q_1 = -z\ell_2$, $q_2 = z\ell_1$, and $\ell = (\ell_1, \ell_2, 0, \dots, 0)$. Note that ℓ_1 and ℓ_2 must be independent linear forms or else q_1 and q_2 would not be independent. On the other hand, we know that $\sum_{i=1}^{g+1} h_i q_i = 0$ so that $(\ell_1h_2 - \ell_2h_1)z \in (q_3, \dots, q_{g+1})$. We claim that z is a nonzerodivisor modulo (q_3, \dots, q_{g+1}) so that $\ell_1h_2 - \ell_2h_1 \in (q_3, \dots, q_{g+1})$.

To see that the claim holds, we first note that $\text{ht}(q_3, \dots, q_{g+1}) = g-1$ so that (q_3, \dots, q_{g+1}) is a complete intersection. Indeed, if this is not the case, then since $I \subseteq (z, q_3, \dots, q_{g+1})$ we would have $\text{ht } I \leq \text{ht}(q_3, \dots, q_{g+1}) + 1 \leq g-1$ by Krull's Height Theorem and [Ser00, III, Prop. 17], contradicting that I is an almost complete intersection. If z were a zerodivisor modulo (q_3, \dots, q_{g+1}) , then there would be an associated prime P of (q_3, \dots, q_{g+1}) such that $I \subseteq (z, q_3, \dots, q_{g+1}) \subseteq P$ so that $\text{ht } I \leq g-1$ as (q_3, \dots, q_{g+1}) is unmixed, again contradicting that I is an almost complete intersection. And so, we see that z must be a nonzerodivisor modulo (q_3, \dots, q_{g+1}) as claimed. Write $\ell_1h_2 - \ell_2h_1 = a_3q_3 + \dots + a_{g+1}q_{g+1}$ for some $a_i \in k$. If $a_i = 0$ for all i , then $\ell_1h_2 - \ell_2h_1 = 0$ so that $(h_2, -h_1) = b(\ell_2, -\ell_1)$ for some $b \in k$ as ℓ_1 and ℓ_2 are independent linear forms. In that case, we can replace h with $h - b\ell$ and assume that $h = (0, 0, h_3, \dots, h_{g+1})$ so that q_3 is a zerodivisor modulo (q_4, \dots, q_{g+1}) . However, we claim that this is impossible. Indeed, by arguing as above, we see that $\text{ht}(q_4, \dots, q_{g+1}) = g-2$ so that (q_4, \dots, q_{g+1}) is a complete intersection, and so, if q_3 were a zerodivisor modulo (q_4, \dots, q_{g+1}) , there would be an associated prime P of (q_4, \dots, q_{g+1}) such that $(q_3, \dots, q_{g+1}) \subseteq P$ so that $\text{ht}(q_3, \dots, q_{g+1}) \leq g-2$ as (q_4, \dots, q_{g+1}) is unmixed, contradicting our earlier observation. Hence, after relabeling, we may assume that $a_3 \neq 0$. Replacing q_3 with $a_3q_3 + \dots + a_{g+1}q_{g+1} = \ell_1h_2 - \ell_2h_1$, we see that $h = (h_1, h_2, -z, 0, \dots, 0)$ and $I = I_2(M) + (q_4, \dots, q_{g+1})$ where M is the matrix of linear forms in (3.1) with $v = 0$.

In both of the above cases, it is easily checked that the Koszul syzygies involving any two of q_1, q_2, q_3 are non-minimal. Let $W' \subseteq U_4$ denote the k -span of the other Koszul syzygies. If $W' \cap S_+U \neq 0$, then there are linear forms u and w such that $u\ell + wh \in W'$ is nonzero.

Write

$$u\ell + wh = \sum_{j=4}^{g+1} [b_{1,j}(q_j e_1 - q_1 e_j) + b_{2,j}(q_j e_2 - q_2 e_j)] + \sum_{3 \leq i < j \leq g+1} b_{i,j}(q_j e_i - q_i e_j)$$

for some $b_{i,j} \in k$. Since $b_{i,j} \neq 0$ for some $j \geq 4$, reading off the j -th coordinate of the above equality yields a linear dependence relation on the q_i , which is a contradiction. Hence, we must have $W' \cap S_+ U = 0$ so that all of the Koszul syzygies involving at least one of q_4, \dots, q_{g+1} are part of a minimal set of generators for U . By Proposition 2.8 and Lemma 2.5, it follows that $U = \text{Syz}_1^S(I)$ is minimally generated by all the Koszul syzygies involving at least one of q_4, \dots, q_{g+1} together with the linear syzygies ℓ and h .

If $f_{g+1} \in ((q_1, \dots, q_g) : q_{g+1})$, then we can write $f_{g+1} q_{g+1} = -\sum_{i=1}^g f_i q_i$ for some $f_i \in S$ so that $(f_1, \dots, f_{g+1}) \in \text{Syz}_1^S(I)$. It follows from the preceding paragraph that $f_{g+1} \in (q_1, \dots, q_g)$ so that q_{g+1} is regular on $R' = S/(q_1, \dots, q_g)$. As $\text{reg}_{R'} R = 1$, it follows from Corollary 2.4 that R' is also Koszul. Moreover, because we can obtain the resolution of R over S by taking the mapping cone of multiplication by q_{g+1} on the resolution of R' over S , it follows that $\beta_{2,3}^S(R') = 2$ and that $(\ell_1, \ell_2, v, 0, \dots, 0)$ and $(h_1, h_2, -z, 0, \dots, 0)$ are the independent linear syzygies on q_1, \dots, q_g . Hence, induction on g implies that q_4, \dots, q_{g+1} is a regular sequence on $S/I_2(M)$. In particular, we see that $g = \text{ht } I = \text{ht } I_2(M) + g - 2$ so that $\text{ht } I_2(M) = 2$. Conversely, if $I = I_2(M) + (q_4, \dots, q_{g+1})$ for some 3×2 matrix of linear forms M with $\text{ht } I_2(M) = 2$ and some regular sequence of quadrics q_4, \dots, q_{g+1} on $S/I_2(M)$, then $S/I_2(M)$ has a Hilbert-Burch resolution by [BH93, 1.4.17] so that $\text{reg}_S(S/I_2(M)) = 1$, and it follows from Corollary 2.4 that $S/I_2(M)$, and hence also $R = S/I$, is Koszul.

If F_\bullet denotes the minimal free resolution of $S/I_2(M)$ over S , we obtain the minimal resolution of R by repeatedly taking the mapping cone of multiplication by q_{i+1} on the resolution of $S/(q_1, \dots, q_i)$. Since taking the mapping cone of multiplication by q_{i+1} is the same as tensoring with the Koszul complex on q_{i+1} , we see that $F_\bullet \otimes_S K_\bullet(q_4, \dots, q_{g+1})$ is the minimal free resolution of R over S , from which the Betti table is easily deduced. In particular, we have

$$\beta_i^S(R) = 2 \binom{g-1}{i-1} + \binom{g-1}{i} = \binom{g}{i} + \binom{g-1}{i-1} \leq \binom{g}{i} + \binom{g}{i-1} = \binom{g+1}{i}$$

Similarly, the multiplicity of $S/(q_1, \dots, q_{i+1})$ is twice the multiplicity of $S/(q_1, \dots, q_i)$ for $i \geq 3$, and so, since $e(S/I_2(M)) = 3$, we see that $e(R) = 3 \cdot 2^{g-2}$. \square

In the next section, we will show that every Koszul almost complete intersection has at most two linear syzygies so that the above results give a complete classification of Koszul almost complete intersections, and therefore, Question 1.1 has an affirmative answer for Koszul almost complete intersections with any number of generators. Assuming this result for the time being, we have the following corollary.

Corollary 3.4. *Koszul almost complete intersections are LG-quadratic.*

Proof. Let $R = S/I$ be a Koszul almost complete intersection, and assume first that $\beta_{2,3}^S(R) = 2$ so that $I = I_2(M) + (q_4, \dots, q_{g+1})$ for some 3×2 matrix $M = (m_{ij})$ of linear forms and q_4, \dots, q_{g+1} a regular sequence of quadrics on $S/I_2(M)$. Set $\tilde{S} = S[X][y_4, \dots, y_{g+1}]$ where $X = (x_{ij})$ is a 3×2 generic matrix, $\tilde{I} = I_2(X) + (y_4^2 + q_4, \dots, y_{g+1}^2 + q_{g+1})$, and $A = \tilde{S}/\tilde{I}$. If we choose a lexicographic order on \tilde{S} with $x_{1,2} > x_{1,1} > x_{2,2} > x_{2,1} > x_{3,2} > x_{3,1}$ and y_i greater than the variables in S for all i , it follows from [Eis95, 15.15] that $\text{in}_>(\tilde{I}) = \text{in}_>(I_2(X)) + (y_4^2, \dots, y_{g+1}^2)$ so that the 2-minors of X together with the $y_i^2 + q_i$ are a Gröbner basis for \tilde{I} by [Stu90]. Hence, A is G-quadratic. Moreover, we also know that the $y_i^2 + q_i$ form a regular sequence on $\tilde{S}/I_2(X)$, and since the latter ring is Cohen-Macaulay, we see that A is Cohen-Macaulay. If J denotes the ideal of A generated by the linear forms $x_{ij} - m_{ij}$ and y_s for $i = 1, 2, 3$, $j = 1, 2$, and $4 \leq s \leq g+1$, then $A/J \cong R$ so that R will be LG-quadratic if the linear forms generating J are a regular sequence. Since A is Cohen-Macaulay and \tilde{I} is also an almost complete intersection of height g , this follows from the fact that $\text{ht } J = \dim A - \dim R = \dim \tilde{S} - \dim S = g+4$ is the number of generators of J .

Assume now that $\beta_{2,3}^S(R) = 1$ so that $I = (xz, zw, q_3, \dots, q_{g+1})$ for some linear forms x, z , and w and q_3, \dots, q_{g+1} a regular sequence of quadrics on $S/(xz, zw)$. In this case, we define $S_i = S[y_{i+1}, \dots, y_{g+1}]$ and $A_i = S_i/I_i$ for $0 \leq i \leq g+1$, where

$$\begin{aligned} I_0 &= (y_1z, y_2z, y_3^2 + q_3, \dots, y_{g+1}^2 + q_{g+1}) \\ I_1 &= (xz, y_2z, y_3^2 + q_3, \dots, y_{g+1}^2 + q_{g+1}) \\ I_i &= (xz, zw, q_3, \dots, q_i, y_{i+1}^2 + q_{i+1}, \dots, y_{g+1}^2 + q_{g+1}) \quad (i \geq 2) \end{aligned}$$

As above, we see that $\text{in}_>(I_0) = (\text{in}_>(z)y_1, \text{in}_>(z)y_2, y_3^2, \dots, y_{g+1}^2)$ for any monomial order on S_0 in which the y_i are greater than every monomial in S so that the generators of I_0 are a Gröbner basis and A_0 is G-quadratic. In addition, we have $A_{g+1} = R$ and $A_i/(y_{i+1}) \cong A_{i+1}$ for all $i < g+1$. An initial ideal argument as above shows that $y_{i+1}^2 + q_{i+1}, \dots, y_{g+1}^2 + q_{g+1}$ is a regular sequence on $S_i/(xz, zw, q_3, \dots, q_i)$ for $i \geq 2$, and similarly, the $y_j^2 + q_j$ are a regular sequence on $S_0/(y_1z, y_2z)$ and $S_1/(xz, y_1z)$. Consequently, A_i is a Koszul almost complete intersection with $\beta_{2,3}^{S_i}(A_i) = 1$ and $\text{ht } I_i = g$ for all i . It then follows from Theorem 3.1 that the A_i have the same Betti table, hence the same h -polynomial $h(t)$, over their respective polynomial rings S_i . Hence, the Hilbert series of A_i is $H_{A_i}(t) = h(t)/(1-t)^{\dim A_i}$. We then compute that $\dim A_i = \dim S_i - g = \dim S_{i+1} - g + 1 = \dim A_{i+1} + 1$ so that $(1-t)H_{A_i}(t) = H_{A_{i+1}}(t)$ for all $i < g+1$. This implies that the natural sequence $0 \rightarrow A_i(-1) \xrightarrow{y_{i+1}} A_i \rightarrow A_{i+1} \rightarrow 0$ is exact so that y_{i+1} is A_i -regular. Therefore, we see that y_1, \dots, y_{g+1} is an A_0 -sequence, and R is LG-quadratic. \square

4 Linear Syzygies of Quadratic ACI's

The following proposition is similar in spirit to Theorem 3.3. However, there are two important distinctions: We do not assume that R is Koszul, so we lose some information

about the syzygies of the defining ideal I , and to make up for this loss of information, we must assume that the ground field is infinite. But first, we make a simple observation which will be useful in the proof.

Remark 4.1. If $f_1, \dots, f_n \in S$ is a regular sequence of homogeneous forms of the same degree and $f = a_1 f_1 + \dots + a_n f_n$ for some $a_i \in k$ with $a_1 \neq 0$, then $((f_2, \dots, f_n) : f) = ((f_2, \dots, f_n) : f_1)$ so that f, f_2, \dots, f_n is also a regular sequence.

Proposition 4.2. Suppose that k is an infinite field and that $R = S/I$ is an almost complete intersection defined by quadrics with $\beta_{2,3}^S(R) \geq 2$. Then there are quadrics q_1, \dots, q_{g+1} and a 3×2 matrix of linear forms M such that $I = (q_1, \dots, q_{g+1}), q_2, \dots, q_{g+1}$ is a regular sequence, and $I_2(M) = (q_1, q_2, q_3)$.

Proof. Set $g = \text{ht } I$. We note that $g \geq 2$, since otherwise we would have $I = (xz, yz)$ for some linear forms x, y, z so that $\beta_{2,3}^S(R) = 1$. First, we can find quadrics q_1, \dots, q_{g+1} such that $I = (q_1, \dots, q_{g+1})$ and q_2, \dots, q_{g+1} is a regular sequence. Indeed, we can take q_{g+1} to be any quadric in I . Having found quadrics $q_i, \dots, q_{g+1} \in I$ with $i > 2$ forming a regular sequence, we know that I is not contained in any associated prime of (q_i, \dots, q_{g+1}) since the latter ideal is unmixed of height $g - i + 2 < g$. Because I is generated in degree two, this implies $I_2 \not\subseteq P$ for each associated prime P of (q_i, \dots, q_{g+1}) . Since k is infinite, I_2 is not a union of the proper subspaces $(I \cap P)_2$ for $P \in \text{Ass}(S/(q_i, \dots, q_{g+1}))$. Hence, we can find a quadric $q_{i-1} \in I$ so that q_{i-1}, \dots, q_{g+1} is a regular sequence. So by induction we have a regular sequence of quadrics q_2, \dots, q_{g+1} in I , and we can take q_1 to be any other quadric independent from q_2, \dots, q_{g+1} since I is minimally generated by $g + 1$ quadrics.

Let ℓ and h be two independent linear syzygies on the q_i . Then $h_1 \ell - \ell_1 h$ is a syzygy on q_2, \dots, q_{g+1} and, therefore, a linear combination of Koszul syzygies. Write

$$h_1 \ell - \ell_1 h = \sum_{2 \leq i < j \leq g+1} a_{i,j} (q_j e_i - q_i e_j)$$

for some $a_{i,j} \in k$, where e_1, \dots, e_{g+1} denotes the standard basis of $S(-2)^{g+1}$. Note that ℓ_1 and h_1 must be independent linear forms, otherwise we could find a nontrivial linear syzygy on q_2, \dots, q_{g+1} since ℓ and h are independent, but that contradicts that q_2, \dots, q_{g+1} is a regular sequence. If $h_1 \ell - \ell_1 h = 0$, then $(-h_i, \ell_i) = b_i(h_1, -\ell_1)$ for some $b_i \in k$ for all $i \geq 2$ so that $h = h_1(1, -b_2, \dots, -b_{g+1})$. But then $(1, -b_2, \dots, -b_{g+1})$ must be a syzygy on the q_i , contradicting that they are independent quadrics. Hence, we see that $h_1 \ell - \ell_1 h \neq 0$ so that $a_{i,j} \neq 0$ for some i, j . Relabeling q_2, \dots, q_{g+1} if necessary, we may assume that $a_{2,3} \neq 0$. Then by Remark 4.1, we can replace q_3 with $q = h_1 \ell_2 - \ell_1 h_2 = a_{2,3} q_3 + \dots + a_{2,g+1} q_{g+1}$. In exchanging q_3 for q , we must replace ℓ with $\tilde{\ell} = (\ell_1, \ell_2, a_{2,3}^{-1} \ell_3, \ell_4 - a_{2,3}^{-1} a_{2,4} \ell_3, \dots, \ell_{g+1} - a_{2,3}^{-1} a_{2,g+1} \ell_3)$ as

$$0 = \sum_{i=1}^{g+1} \ell_i q_i = a_{2,3}^{-1} \ell_3 q + \ell_1 q_1 + \ell_2 q_2 + \sum_{i=4}^{g+1} (\ell_i - a_{2,3}^{-1} a_{2,i} \ell_3) q_i$$

and we also replace h with the syzygy \tilde{h} defined as above. However, $\tilde{\ell}$ and \tilde{h} are still independent linear syzygies since their first coordinates are independent linear forms. After making the above changes, we have $a_{2,3} = 1$ and $a_{2,i} = 0$ for all $i > 3$. Then $h_1\ell_3 - \ell_1h_3 = -q_2 + a_{3,4}q_4 + \cdots + a_{3,g+1}q_{g+1}$, and we can replace q_2 with $-(h_1\ell_3 - \ell_1h_3)$ as above. In that case, we have $q_2 = -(h_1\ell_3 - \ell_1h_3)$ and $q_3 = h_1\ell_2 - \ell_1h_2$ so that

$$0 = \sum_{i=1}^{g+1} \ell_i q_i = \ell_1(q_1 + \ell_2 h_3 - \ell_3 h_2) + \sum_{i=1}^4 \ell_i q_i$$

implies that $q_1 + \ell_2 h_3 - \ell_3 h_2 \in ((q_4, \dots, q_{g+1}) : \ell_1)$.

We claim that ℓ_1 is a nonzerodivisor modulo (q_4, \dots, q_{g+1}) . If not, then ℓ_1 is contained in an associated prime of (q_4, \dots, q_{g+1}) so that $\text{ht}(\ell_1, q_4, \dots, q_{g+1}) = g - 2$. But then $\text{ht}(\ell_1, h_1, q_4, \dots, q_{g+1}) \leq \text{ht}(\ell_1, q_4, \dots, q_{g+1}) + 1 = g - 1$, and since $(q_2, \dots, q_{g+1}) \subseteq (\ell_1, h_1, q_4, \dots, q_{g+1})$, this contradicts $\text{ht}(q_2, \dots, q_{g+1}) = g$. Therefore, ℓ_1 is a nonzerodivisor modulo (q_4, \dots, q_{g+1}) as claimed so that $q_1 + \ell_2 h_3 - \ell_3 h_2 \in (q_4, \dots, q_{g+1})$. We can then write $\ell_2 h_3 - \ell_3 h_2 = -q_1 + c_4 q_4 + \cdots + c_{g+1} q_{g+1}$ for some $c_i \in k$. Replacing q_1 with $\ell_2 h_3 - \ell_3 h_2$ and setting

$$M = \begin{pmatrix} \ell_1 & h_1 \\ \ell_2 & h_2 \\ \ell_3 & h_3 \end{pmatrix} \quad (4.1)$$

yields $I_2(M) = (q_1, q_2, q_3)$ as wanted. \square

Theorem 4.3. *If $R = S/I$ is a quadratic almost complete intersection, then $\beta_{2,3}^S(R) \leq 2$.*

Proof. Suppose that $\beta_{2,3}^S(R) \geq 3$. Let K be an infinite extension field of k , and for each k -algebra A , set $A_K = A \otimes_k K$. Then $\beta_{2,3}^{S_K}(R_K) = \beta_{2,3}^S(R)$, $\dim R_K = \dim R$, and $IS_K/I(S_K)_+ \cong I/IS_+ \otimes_S S_K \cong I/IS_+ \otimes_k K$ by faithfully flat base change so that IS_K is still a quadratic almost complete intersection, and replacing R with R_K , we may assume that the ground field k is infinite.

By the preceding proposition, there are quadrics q_1, \dots, q_{g+1} for $g = \text{ht } I \geq 2$ and a 3×2 matrix of linear forms M as in (4.1) such that $I = (q_1, \dots, q_{g+1})$, q_2, \dots, q_{g+1} is a regular sequence, and $I_2(M) = (q_1, q_2, q_3)$. We may assume that q_1, q_2, q_3 are the minors of M as in the proof of the proposition. In that case, $\ell = (\ell_1, \ell_2, \ell_3, 0, \dots, 0)$ and $h = (h_1, h_2, h_3, 0, \dots, 0)$ are two independent linear syzygies on the q_i . Let u be a linear syzygy independent from ℓ and h . By arguing as in the proof of the preceding proposition, we see that u_1, ℓ_1 , and h_1 are independent linear forms and that $u_1\ell - \ell_1u \neq 0$.

We claim that $u_1\ell - \ell_1u$ is linear independent from $h_1\ell - \ell_1h$. If not, then $u_1\ell - \ell_1u = c(h_1\ell - \ell_1h)$ for some nonzero $c \in k$. Setting $\tilde{u} = u - ch$ and rearranging the preceding equality, we have that \tilde{u} is a linear syzygy independent from ℓ and h with $\tilde{u}_1\ell - \ell_1\tilde{u} = 0$, which is impossible as already noted in the previous paragraph. Hence, $u_1\ell - \ell_1u$ is independent from $h_1\ell - \ell_1h$ as claimed. In particular, we note that $g \geq 3$ since there cannot be two independent

quadratic syzygies on the regular sequence q_2, q_3 . Write

$$u_1\ell - \ell_1u = \sum_{2 \leq i < j \leq g+1} b_{i,j}(q_j e_i - q_i e_j)$$

for some $b_{i,j} \in k$. Since $h_1\ell - \ell_1h = (0, q_3, -q_2, 0, \dots, 0)$ by assumption, we must have $b_{i,j} \neq 0$ for some $(i, j) \neq (2, 3)$, otherwise we would have a contradiction to the claim. In fact, by replacing u with $u - b_{2,3}h$, we may assume that $b_{2,3} = 0$.

Next, we claim that there is a $j \geq 4$ such that $b_{2,j} \neq 0$ or $b_{3,j} \neq 0$. If not, the first three coordinates of $u_1\ell - \ell_1u$ must be zero so that $u_1\ell - \ell_1u = (0, 0, 0, -\ell_1u_4, \dots, -\ell_1u_{g+1})$. But this implies that (u_4, \dots, u_{g+1}) is a linear syzygy on q_4, \dots, q_{g+1} , which is impossible since q_4, \dots, q_{g+1} is a regular sequence. Hence, relabeling if necessary, we may assume that $b_{2,4} \neq 0$ so that we can replace q_4 with $u_1\ell_2 - \ell_1u_2 = b_{2,4}q_4 + \dots + b_{2,g+1}q_{g+1}$.

Finally, we claim that there is a $j \geq 5$ such that $b_{3,j} \neq 0$. If not, then $u_1\ell_3 - \ell_1u_3 = b_{3,4}q_4 = b_{3,4}(u_1\ell_2 - \ell_1u_2)$ as $b_{2,3} = 0$. But this implies that $(b_{3,4}u_2 - u_3, \ell_3 - b_{3,4}\ell_2) = r(u_1, -\ell_1)$ for some $r \in k$ as ℓ_1 and u_1 are independent linear forms. In particular, we see that $\ell_3 \in \text{Span}\{\ell_1, \ell_2\}$ so that $I \subseteq (\ell_1, \ell_2, q_5, \dots, q_{g+1})$. However, $\text{ht}(\ell_1, \ell_2, q_5, \dots, q_{g+1}) \leq g - 1$, which contradicts $\text{ht } I = g$. Hence, we must have $g \geq 4$, and after relabeling, we may assume that $b_{3,5} \neq 0$ and replace q_5 with $u_1\ell_3 - \ell_1u_3 = b_{3,4}q_4 + b_{3,5}q_5 + \dots + b_{3,g+1}q_{g+1}$. But then $I \subseteq (\ell_1, \ell_2, \ell_3, q_6, \dots, q_{g+1})$ and $\text{ht}(\ell_1, \ell_2, \ell_3, q_6, \dots, q_{g+1}) \leq g - 1$, contradicting that $\text{ht } I = g$. Therefore, we must have $\beta_{2,3}^S(R) \leq 2$. \square

5 Future Directions

Using our main result, we have reason to believe that Question 1.1 can be answered affirmatively for Koszul algebras defined by $g = 4$ quadrics. However, Example 2.2 points to unexpected difficulties when $g = 5$.

Our work also has unintended connections to various other conjectures of interest. For example, the Buchsbaum-Eisenbud-Horrocks Conjecture asks whether $\beta_i^S(R) \geq \binom{c}{i}$ for all i if $c = \text{ht } I$. This conjecture is already known to hold for quotients by monomial ideals. An even larger lower bound $\beta_i^S(R) \geq \binom{c}{i} + \binom{c-1}{i-1}$ was given for monomial ideals I of finite colength that are not complete intersections by Charalambous and Evans in [Cha91][CE91] and for almost complete intersections directly linked to a complete intersection by Dugger in [Dug00, 2.3]. Among Koszul almost complete intersections $R = S/I$, those with one linear syzygy cannot be directly linked to a complete intersection since they are not Cohen-Macaulay. Nonetheless, they still satisfy this larger bound. For Koszul ACI's with two linear syzygies, at least when the ground field is infinite, the results of the previous section show that I is directly linked to the complete intersection $(\ell_1, h_1, q_4, \dots, q_{g+1})$, and Theorem 3.3 yields that Dugger's result is sharp. A total rank version of the Charalambous-Evans bound $\sum_i \beta_i(R) \geq 2^c + 2^{c-1}$ has been studied in [CEM90], and Boocher and Seiner have recently established this bound for all monomial ideals which are not complete intersections. Our

work affirmatively answers a couple questions they pose [BS17, 1.2, 1.3] in the Koszul ACI case.

Another consequence of our structure theorem is that the EGH Conjecture holds for Koszul almost complete intersections in a strong form similar to [CCV14, 2.1]. This conjecture asks whether, given a graded ideal $I \subseteq S = k[x_1, \dots, x_n]$ containing a homogeneous regular sequence f_1, \dots, f_r of degrees $2 \leq d_1 \leq \dots \leq d_r$, there is a monomial ideal J containing $x_1^{d_1}, \dots, x_r^{d_r}$ and having the same Hilbert function as I . The EGH Conjecture is known to hold when I is a quadratic monomial ideal by the preceding paper, when I is a complete intersection of quadrics, or when I is generated by products of linear forms [Abe15], which covers quadratic ideals of height one. To this list, we add that, if I defines a Koszul almost complete intersection, we can simply take $J = (x_1^2, \dots, x_g^2, x_g x_{g+1})$ or $J = (x_1^2, \dots, x_g^2, x_{g-1} x_g)$ according to whether I has one or two linear syzygies respectively. Note for the former case that $g + 1 = \text{pd}_S R \leq n$ by Hilbert's Syzygy Theorem.

Given the previous and new evidence for the above conjectures in the Koszul case, it is natural to ask whether they hold at the very least for Koszul algebras in general.

Acknowledgments

The author would like to thank his advisor, Hal Schenck, for many helpful comments and discussions throughout the development of this work. He would also like to thank Aldo Conca for pointing out a mistake in an earlier draft of this paper and the anonymous referee for helping to simplify the exposition and clarify the history of various results cited. Evidence for the results in this paper was provided by several computations in Macaulay2 [M2].
